(54) Title: A SEPARATING APPARATUS FOR A VACUUM CLEANER

WO 02/067750 A1

(57) Abstract: A bagless vacuum cleaner (10) comprises a separating unit (20) for separating dirt and dust from a dirt-laden airflow which is drawn in by the cleaner. The separating unit (20) has a chamber (205) with a collection area for collecting dirt and dust which is separated from the airflow. A base (210) of the separating unit (20) is movable between a closed position (Fig. 3) and an open position. The closure member (210) is released by a trigger (220) and a linking mechanism (222, 230, 260). The linking mechanism (230) is located centrally within an insert (206) in the chamber. The insert (206) is a collection area for dust from a second separating stage (240).

A Separating Apparatus for a Vacuum Cleaner

This invention relates to a separating apparatus for a bagless vacuum cleaner and to a
5 vacuum cleaner which incorporates the separating apparatus.

Vacuum cleaners which separate dirt and dust from an airflow without the use of a filter
bag, so-called bagless vacuum cleaners, are becoming increasingly popular. Most
bagless cleaners use cyclonic or centrifugal separation to spin dirt and dust from the
10 airflow. By avoiding the use of a filter bag as the primary form of separation, it has
been found possible to maintain a consistently high level of suction, even as the
collecting chamber fills with dirt.

The principle of cyclonic separation in domestic vacuum cleaners is described in a
15 number of publications including EP 0 042 723. In general, an airflow in which dirt and
dust is entrained enters a first cyclonic separator via a tangential inlet which causes the
airflow to follow a spiral or helical path within a collection chamber so that the dirt and
dust is separated from the airflow. Relatively clean air passes out of the chamber whilst
the separated dirt and dust is collected therein. In some applications, and as described
20 in EP 0 042 723, the airflow is then passed to a second cyclone separator which is
capable of separating finer dirt and dust than the upstream cyclone. The airflow is
thereby cleaned to a greater degree so that, by the time the airflow exits the cyclonic
separating apparatus, the airflow is almost completely free of dirt and dust particles.

25 While bagless vacuum cleaners are successful in maintaining a consistently high level
of suction, the absence of a bag can make it difficult to dispose of the dirt and dust
which is collected by the cleaner. When the separating chamber of a bagless cleaner
becomes full, a user typically removes the collecting chamber from the chassis of the
machine, carries the chamber to a dust bin or refuse sack and tips the chamber upside
30 down. Often dirt and dust is densely packed inside the collecting chamber and it may
be necessary for a user to manually dislodge the dirt by reaching into the chamber and

pulling at the collected mass of dust and fibres, or to shake or bang the collecting chamber against the side of a dustbin. In some cases, this can cause a fair amount of mess.

- 5 Some solutions to this problem have been proposed. US 5,090,976 describes the use of a disposable liner which can be fitted inside the cyclonic separating chamber. When the liner is full, the liner is lifted out of the chamber and disposed of. WO 98/10691 describes a cyclonic collection chamber where a bag is retained, in a collapsed state, in the base of the collection chamber. When the collection chamber is full, the base is
10 unscrewed from the chamber so that the bag can extend downwardly from the base. Dirt and dust slides out of the collecting chamber into the bag and the bag can then be sealed and separated from the collecting chamber for disposal. Both of these solutions have a disadvantage in that they require a user to keep a supply of spare bases or liners, which adds to the cost of maintaining the machine.
- 15 EP 1 023 864 describes a dust-collecting device for a cyclonic vacuum cleaner. The dust-collecting chamber can be removed from the chassis of the cleaner for emptying. A bottom lid of the dust-collecting chamber is attached by way of a hinge to the remainder of the chamber and the lid can be released by pressing a release button. A
20 ribbed cylindrical filter is fitted inside the dust-collecting chamber and is rotatable within the chamber to encourage the release of dirt which is stored in the chamber. One embodiment of EP 1 023 864 describes how a release lever for releasing the bottom lid can be located remotely from the lid, as part of the grip for the chamber.
- 25 It is desirable to provide a lid release control which is located remotely from the lid itself as a user is spaced from dirt and dust when the chamber is emptied. However, remotely locating the lid release control has the disadvantage of accommodating the release mechanism which links the control and the lid.
- 30 Thus, the present invention seeks to provide a separating apparatus for a bagless vacuum cleaner in which this disadvantage is mitigated.

- Accordingly, a first aspect of the present invention provides a separating apparatus for a bagless vacuum cleaner comprising a separation chamber having an inlet for receiving a dirt-laden airflow, an air outlet, a collection area for collecting, in use, dirt and dust
- 5 which has been separated from the airflow and wherein part of the chamber wall in the region of the collection area is a closure member which is movable between a closed position in which the closure member seals the chamber and an open position in which dirt and dust can escape from the collection area, the chamber further comprising releasing means for releasing the closure member from the closed position, the releasing
- 10 means comprising a manually operable actuating member which is located remotely from the closure member and a linking mechanism which couples the actuating member to the closure member and wherein the linking mechanism is located within the separation chamber.
- 15 The positioning of the linking mechanism within the separation chamber has the advantage that the linking mechanism does not need to be housed in a dedicated conduit on the outer wall of the collection chamber. This simplifies the construction of the chamber and avoids an unnecessary cluttering of the outer wall of the chamber. It also reduces the physical size of the separating apparatus. Also, where the chamber has a
- 20 transparent outer wall, the provision of the linking mechanism within the separation chamber minimises any obstruction to a user's view of the collection area.

Preferably, the linking mechanism is centrally positioned within the separation chamber. This helps to maintain the balance of the chamber, which reduces stress on a user's hand

25 when they hold the chamber and operate the releasing means. Also, it has been found that the presence of the linking mechanism at a central position within the separator has a minimal effect on the separation efficiency of the separator. This is because, in a cyclonic separator, the majority of the dirt-laden airflow is near the outer wall of the separator.

In its simplest form, the linking mechanism can simply be located within the separation chamber. However, it is preferable that the linking mechanism is located within an insert that fits within the separation chamber. This insert could simply serve to shield the linking mechanism from dust and support the linking mechanism. Alternatively, the 5 insert could itself form a second collection area, such as the collection area for a second stage of separation. The second stage of separation can take place upstream of the second collection area or within the second collection area.

The term 'bagless' is intended to cover a broad range of vacuum cleaners which have a 10 reusable collecting chamber, and includes, inter alia, cleaners which separate dirt and dust by way of cyclonic, centrifugal or inertial separation.

It is convenient for the actuating member to be located adjacent a handle for carrying the separator. This allows a user to carry and empty the separator with one hand.

15 Preferably agitating means are provided for agitating dirt held within the collection area, the agitating means being operable by the actuating member. This helps to dislodge any dirt that may have become 'stuck' in the collection area. Also, a user does not need to separately operate the releasing and the agitating means.

20 Preferably the closure member is pivotably fixed to the chamber. Also, it is preferable for the pivot to be located on the side of the chamber nearest the user such that the user is shielded from any dust which is released from the chamber.

25 The separating apparatus is preferably a cyclonic separator where dirt-laden air is spun at high speed to centrifugally separate dirt from the airflow but it can be any form of bagless separator where the collection chamber is reused after it has been emptied.

A further aspect of the invention provides a vacuum cleaner incorporating a separating 30 apparatus of the kind described above.

Embodiments of the invention will now be described, by way of example only, with reference to the accompanying drawings in which:

Figure 1 shows a bagless vacuum cleaner;

5

Figure 2 shows just the dirt and dust separation unit of the vacuum cleaner of Figure 1;

Figure 3 is a cross-section along line A-A of the dirt and dust separation unit of Figure 2, with the base of the unit in a closed position;

10

Figure 4 shows the same cross-section as Figure 3 but with the base in a partially open position;

15

Figure 5 shows the same cross-section as Figure 3 but with the base in a fully open position;

Figure 6 is a cross-section through the dirt and dust separation unit mounted on the chassis of the vacuum cleaner;

20

Figure 6A is a more detailed view of the same cross-section as Figure 6, showing the feature on the chassis which inhibits movement of the trigger release mechanism;

Figure 7 is a more detailed view of the lower part of the cross-section of Figure 3;

25

Figure 8 shows how dirt and dust accumulates in the dirt and dust separation unit;

Figures 9A – 9C show the seal of the vacuum cleaner in use; and,

Figures 10A – 10D show alternative embodiments of the invention.

30

Referring to Figures 1 to 3, a vacuum cleaner 10 has a main chassis 50 which supports dirt and dust separation apparatus 20. The lower part of the cleaner 10 comprises a cleaner head 22 for engaging with the floor surface. The cleaner head has a downwardly facing suction inlet and a brush bar is mounted in the mouth of the inlet for agitating the floor surface. The cleaner head is pivotably mounted to a motor housing 24 which houses the motor and fan of the cleaner. Support wheels 26 are mounted to the motor housing for supporting the cleaner and allowing movement across a floor surface. A spine of the chassis 50 extends upwardly from the motor housing 24 to provide support for the components of the cleaner. A cleaning wand 42 having a second dirty air inlet 43 is connected by way of a hose (not shown) to the chassis at the base of the spine 50. The wand 42 is releasable from the spine 50 so as to allow a user to carry out above-the-floor cleaning and cleaning in places which are inaccessible by the main cleaning head 22. When the wand is fixed to the spine 50, the wand 42 forms the handle of the cleaner and a handgrip 40 at the remote end of the wand 42 allows a user to manoeuvre the cleaner. These features of the cleaner are well known and have been well documented elsewhere and can be seen, for example, in cleaners which are manufactured by DYSON™, and thus will not be described in any further detail.

Dirty air from the cleaner head 22 or wand inlet 43 is carried to the separator unit 20 by inlet conduit 28 and inlet 30. Separator 20 is a cyclonic separator which spins dirt, dust and other debris out of the airflow by centrifugal separation. One particular form of separator unit 20 is shown in detail in the figures as a preferred embodiment but it should be understood that there are many other ways in which the separator could be constructed. In the illustrated separator unit 20, airflow passes through a first separation stage and then a second separation stage. The first separation stage is a substantially cylindrically-walled cyclonic chamber 205 whose purpose is to separate large debris and dirt from the airflow. Inlet 30 is arranged to direct dirty air into the chamber 205 in a tangential direction to the wall of the chamber. Fins or baffles 207 extend radially outwardly from a central core of the chamber and serve to discourage separated dirt or dust from becoming re-trained in the airflow when the vacuum cleaner is first started. The outlet of the first separation stage is a shroud 235, i.e. an apertured annular wall

mounted coaxially inside the chamber 205. The area on the inner side of the shroud leads to the second separation stage. The second separation stage is a set of tapered cyclonic chambers 240 which are arranged in parallel with one another. Each cyclonic chamber 240 has a tangential inlet 242, an outlet 243 for separated dirt and dust and a cleaned air outlet 244. Each of the cleaned air outlets 244 of the cyclonic chambers 240 communicate with an outlet conduit such that air from the individual outlets of the parallel cyclonic chambers is recombined into a single flow. The outlet conduit mates with a port on the chassis spine 50 when the separator unit 20 is fitted to the chassis.

- 10 In use dirty air which is laden with dirt, dust and other debris enters the first separation stage via inlet 30 and follows a spiral path around the chamber 205. The centrifugal force acting on the material in the airflow causes the larger debris and dirt to be separated from the airflow. This separated material collects at the base of the chamber 205, against base 210, due to a combination of gravity and the pressure gradient which exists in chamber 205 while the cleaner is in operation. The airflow passes through the shroud 235. The shroud 235 causes air to perform a sharp change of direction and causes fibrous material to collect on the outer wall of the shroud 235. The airflow passes to the second separation stage where it is divided between the cyclonic chambers. Air enters a respective one of the chambers via a tangential inlet and is then constrained to follow a spiral path of decreasing radius which greatly increases the speed of the airflow. The speed is sufficient to separate dirt and extremely fine dust from the airflow. The separated dirt and dust exits the cyclonic chambers 240 via outlets 243 which communicate with a central conduit 245. Dirt and dust falls, under gravity, towards the base of conduit 245 and collects at the lower end of the conduit 245 adjacent the base 210 in region 270 (Figure 8). Cleaned air from the parallel chambers 245 is recombined into a single flow and is channelled out of the separator unit 20, down the spine 50 of the chassis and through a pre-motor filter, fan and post-motor filter before finally being exhausted from the cleaner.
- 20
- 25
- 30 It should be understood that the second separation stage need not be a set of parallel cyclonic chambers 240. The second separation stage could be a single tapered cyclonic

chamber which can fit inside the cylindrical chamber of the first separation stage, as shown in EP 0 042 723. Alternatively, the second separation stage could be a further cylindrical cyclone or it could be omitted altogether. The first separation stage may be a tapered chamber rather than the cylindrical one described. However, in each of these
5 alternatives, dirt and dust will be separated from an airflow without the use of a filter bag and will collect in a collection area.

The separator unit 20 is supported by the chassis 50 and is releasably held upon the chassis by a catch 280, shown more clearly in Figure 6A. The separator unit 20 is
10 shown by itself in Figures 2 - 5. The separator unit 20 is releasable from the chassis to allow the separator to be emptied. A handle 202 is provided at the top of the separator unit 20 for allowing a user to carry the unit 20. The base 210 of the separator unit is movable between a closed position (shown in Figures 2, 3) and an open position (shown partially open in figure 4 and fully open in Figure 5) to permit emptying of the unit 20.
15 The base 210 is hinged 214 to the cyclone chamber 205 to allow pivotal movement between the base 210 and chamber 205. Two separate collection areas lie adjacent to the base 210. The first collection area is the annular region between the cylindrical chamber wall 205 and the inner wall 206 at the lower end of the separator. The second collection area 270 is the area within the tube-like part 206. Thus, when base 210
20 opens, material empties from both of the collection areas. The outer annular edge of the base 210 has a radially inwardly extending slot to hold a seal 212. In use, with the base closed, the seal 212 fits tightly against the inner wall of the chamber 205 to maintain an air and dust-tight seal. A second, collar shaped, seal 213 extends axially outwardly from the lower annular edge of part 206 such that it fits tightly against the axially
25 extending wall of the raised central cap of the base 210. The base 210 is held in the closed position by a lock mechanism 260, 262. The locking mechanism is controlled by a manually operable trigger 220. A linking mechanism 222, 223, 224, 230 joins the trigger 220 to the lock mechanism. Trigger 220 is received in a vertically extending channel on the spine-facing side of the separator which confines the trigger to follow a vertical movement. A lug on the trigger cooperates with a lever arm 222. The lever is pivotably fixed to the housing such that the remote end of the lever arm pushes
30

downwardly against the upper end 231 of push rod 230. The push rod 230 is resiliently biased by spring 223 in the position shown in Figure 3 and can be displaced downwardly (to the position shown in Figure 4) against the action of the spring 223 when the trigger is pulled. Spring 223 is held in a cavity of the housing and respective ends of the spring 223 act against the end wall of the cavity and the flange which is carried by the push rod 230 near end 231. The linking mechanism is shielded from dust by a gaiter 224, which is attached to the push rod 230 and the housing of the separator unit. The gaiter 224 stretches as the push rod moves downwardly, maintaining a dust-tight shield for the mechanism behind the gaiter 224. Push rod 230 is centrally located, and passes directly through the tube-like dust collecting conduit 245. Thus, the release mechanism is hidden from view. The central position of the release mechanism also helps to maintain the balance of the separator unit 20, which reduces stress on a user's hand when they hold the separator unit 20 and operate the release mechanism. The end of the push rod 230 nearest the base 210 is supported by a short guide channel 290 which is supported centrally within the tube-like part 206 by arms 292.

The lowermost end of the push rod has an inclined face which cooperates with a similarly inclined face on the catch 260 at the base. Catch 260 is pivotably mounted to the base and can be displaced, against the bias of spring 262, to the position shown in Figure 4. The catch has a hook 263 which engages with a corresponding hooked feature 264 on the central part of the base 210 so as to hold the base 210 in the closed position. The lowermost surface of the catch 260 is curved such that when the base 210 is pushed towards the closed position the catch 260 is displaced, allowing the hook 264 on the base 210 to engage with the hook 263 on the catch 260.

25

It will be appreciated that the trigger, linking mechanism and lock can be realised in many alternative ways. For example, the trigger 220 could be linked directly to the push rod 230, rather than being indirectly linked by the lever 222.

30 The lower end of the push rod 230 also carries an agitator 250. The agitator 250 is fixed to the push rod and thus moves upwardly and downwardly with the push rod as the

trigger 220 is operated. In use, a plug of dirt and dust may form at the lower end of the second collection area, next to base 210. The agitator 250 has radially outwardly extending fins. In use, movement of the agitator will either push the plug or break the plug into smaller parts which can then fall out of the collection area. The inner surfaces 5 of the collection tube are smooth and tapered to discourage dirt from settling. The agitator could be more elaborate than the one shown here. For example, the agitator could be arranged to rotate about the longitudinal axis of the push rod 230 as the push rod moves upwards or downwards. A second agitator could be provided in the first collection area, the second agitator also being linked to the push rod or release 10 mechanism. The cutting effect of the agitator on a plug of material can be improved by forming sharp or pointed edges on the agitator.

To ensure an air and dust-tight seal around the base, the seal 212 fits tightly against the chamber. This may cause the base to 'stick' in the closed position when the catch 260 is 15 released. The push rod 230 has a sufficient length such that, when it is operated, it moves downwardly towards the catch 260, operates catch 260 and then continues to move towards the base 210, pushing against the base, overcoming the resistance of the seal 212 against the chamber wall 205 and thus pushing the base 210 open.

20 In use, a user removes the separator unit 20 from the chassis by operating release member 280 and carries the separator unit 20, by way of handle 202, to a dust bin or refuse sack. The lower end of the separator unit is held over or within the dust bin or sack and the trigger 220 is pulled. This causes the base 210 to swing open and dirt, dust and debris which has been collected in the chamber 205 falls out of the unit 20 into the 25 bin. Due to the distance between the handle and base, and the direction in which the dirt falls from the unit 20, a user is not brought into contact with the dirt. As the dirt collects against the part of the chamber which opens, i.e. base 210, the dirt falls out of the chamber 205 with little or no additional effort by a user. Fine dust collected within the second stage collector 270 can be fully cleared by the user operating trigger 220 30 several times. This will operate agitator 250.

- Referring again to Figure 8, the region within tube-like part 206 forms a second stage collection area. For good cyclonic separation, it is important that the second stage collection area is sealed with respect to the first stage collection area which surrounds it.
- 5 Collar-shaped seal 213 seals against the base 210 to achieve the seal between the first and second stage collection areas. A particular problem with sealing against the base 210 is that base is exposed to dirt and dust which can prevent a reliable seal from being achieved. Figures 9A – 9C show, in more detail, how the seal 213 fits against the base 210 during use.
- 10 Base 210 of the separator unit 20 has an inwardly tapering wall 210a and an upper wall 210b. The collar shaped seal 213 has a diameter D_S which is narrower than the diameter D_B of the base 210 at the position where the seal 213 rests when the base 210 is fully closed. Seal 213 is formed from a resilient material such as a thermoplastic elastomer (TPE).
- 15 Figure 9A – 9C show the base 210 being returned to a closed position against the chamber 205 after a user has emptied the chamber 205. In Figure 9A it can be seen that a layer of fine dust 300 covers the base 210. In Figure 9B the base 210 has been moved nearer to its final, closed, position. The lower end of seal 213 has stretched to accommodate wall 210a of the base 210. Due to the tight fit between the leading edge 213a of the seal 213 and the wall 210a, the layer of dust on the outermost surface of the wall 210a is pushed downwardly by the leading edge 213a of the seal 213. Finally,
- 20 Figure 9C shows the base 210 in a closed position. The seal 213 has moved further down the wall 210a of the base 210. A significant portion of the seal 213 now lies firmly against a portion of the wall 210a which has previously been cleaned by the leading edge of the seal 213a. Dust which has been displaced from the surface of the wall 210a accumulates 310 beneath the leading edge 213a of seal 213. Thus, a reliable seal is
- 25 achieved between seal 213 and base 210 even in the presence of dirt and dust.
- 30 Figure 6 shows the separator unit 20 in position on the chassis 50 of the cleaner 10. To ensure that the base 210 is not accidentally opened when the cleaner is in use, the

chassis 50 has a projection 218 which fits inside a notch 217 on the trigger 220 when the separator unit 20 is fitted to the chassis 50. Thus, the trigger 220 is inhibited from operating.

5 Figures 10A – 10D show alternative embodiments of the invention. For ease of comparison, the embodiment which has been described in detail above is represented here in simplified form as Figure 10A. In Figure 10A the linking mechanism 230 is located within a tube 206. Tube 206 serves as an inner rotational surface for the dirt-laden air in the first separation and collection stage and also serves as a collection tube
10 for dust from the second separation stage 240.

Figure 10B shows a much simplified embodiment where the linking mechanism 230 passes through the centre of a single separation and collection area. In use, dirt-laden air swirls about the chamber and separated dirt and dust collects at the base of the
15 chamber. Figure 10C is similar to Figure 10B except that the linking mechanism 230 is located within an insert 400. Insert 400 shields the linking mechanism from dirt and dust in the collection area and can also be used to support the linking mechanism at various positions along its length.

20 Finally, in Figure 10D the linking mechanism is located within an insert 420. Insert 420 is a second separation stage and here takes the form of a tapered cyclonic unit. Dust separated from the airstream by the cyclonic unit 420 collects in a collection area 425 at the base of the cyclonic unit 420. In Figures 10A and 10D the linking mechanism could be housed within an insert which serves a similar purpose to the insert 400 in Figure
25 10C, i.e. to shield the linking mechanism from dust and to support the linking mechanism.

Claims

1. A separating apparatus for a bagless vacuum cleaner comprising a separation chamber having an inlet for receiving a dirt-laden airflow, an air outlet, a collection area for collecting, in use, dirt and dust which has been separated from the airflow and wherein part of the chamber wall in the region of the collection area is a closure member which is movable between a closed position in which the closure member seals the chamber and an open position in which dirt and dust can escape from the collection area, the chamber further comprising releasing means for releasing the closure member from the closed position, the releasing means comprising a manually operable actuating member which is located remotely from the closure member and a linking mechanism which couples the actuating member to the closure member and wherein the linking mechanism is located within the separation chamber.
- 15 2. A separating apparatus according to claim 1 wherein the linking mechanism is located centrally within the separation chamber.
3. A separating apparatus according to claim 1 or 2 wherein the separation chamber is a cyclonic separator.
- 20 4. A separating apparatus according to any one of the preceding claims wherein the linking mechanism is located within an insert that fits within the separation chamber.
- 25 5. A separating apparatus according to claim 4 wherein the insert is a conduit which defines a second collection area.
6. A separating apparatus according to claim 5 further comprising a second separator stage which lies upstream of the second collection area and wherein the second collection area is in communication with a dust outlet of the second separator stage.

7. A separating apparatus according to claim 6 wherein the second separator stage comprises a plurality of cyclonic separators which are arranged in parallel with one another.

5 8. A separating apparatus according to claim 4 or 5 wherein the insert also defines a cyclonic separating unit.

9. A separating apparatus according to claim 8 wherein the cyclonic separating unit has a cross-section which reduces along its length.

10

10. A separating apparatus according to any one of the preceding claims wherein part of the linking mechanism is located outside of the separation chamber and wherein a seal is located at the position where the linking mechanism enters the separation chamber.

15

11. A separating apparatus according to claim 10 wherein the linking mechanism is moveable, in use, to effect the release of the closure member, and wherein the seal is a flexible seal which is attached to the linking mechanism and to the wall of the separation chamber.

20

12. A separating apparatus according to claim 11 wherein the seal is a resiliently flexible gaiter seal.

25

13. A separating apparatus according to any one of the preceding claims further comprising agitating means for agitating dirt held within the collection area and wherein the agitating means is mounted on the linking mechanism.

30

14. A separating apparatus according to any one of the preceding claims wherein the closure member is pivotably attached to the chamber and the releasing means is operable to apply an opening force to the closure member at a position which is spaced from the pivot.

15. A separating apparatus according to any one of the preceding claims wherein the closure member is lockable in the closed position and the releasing means comprises a push rod which is movable to firstly unlock the closure member and secondly to exert
5 an opening force on the closure member.
16. A separating apparatus according to any one of the preceding claims further comprising a handle for carrying the apparatus and wherein the actuating member is located adjacent the handle.
10
17. A separating apparatus according to claim 16 wherein the actuating member is a trigger mechanism which is located beneath the handle.
18. A separating apparatus according to any one of the preceding claims wherein the
15 closure member forms a base of the chamber.
19. A vacuum cleaner incorporating a separating apparatus according to any one of the preceding claims.
20. 20. A separating apparatus for a vacuum cleaner or a vacuum cleaner incorporating a separating apparatus substantially as described herein with reference to the accompanying drawings.

INTERNATIONAL SEARCH REPORT

	International Application No PCT/GB 02/00283
--	---

A. CLASSIFICATION OF SUBJECT MATTER IPC 7 A47L9/16

According to International Patent Classification (IPC) or to both national classification and IPC

B. FIELDS SEARCHED

Minimum documentation searched (classification system followed by classification symbols)

IPC 7 A47L

Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched

Electronic data base consulted during the international search (name of data base and, where practical, search terms used)
--

EPO-Internal, WPI Data, PAJ

C. DOCUMENTS CONSIDERED TO BE RELEVANT
--

Category	Citation of document, with indication, where appropriate, of the relevant passages	Relevant to claim No.
A	EP 1 023 864 A (SANYO ELECTRIC CO) 2 August 2000 (2000-08-02) cited in the application abstract column 7, line 8 - line 33 figures 7-9 ---	1
A	WO 01 05291 A (MATSUMOTO Y ET AL) 25 January 2001 (2001-01-25) figure 18 ---	1
A	US 3 816 983 A (KAJIKAWA S ET AL) 18 June 1974 (1974-06-18) abstract figures 5,8 ---	1
	-/-	

Further documents are listed in the continuation of box C.

Patent family members are listed in annex.

* Special categories of cited documents :

- "A" document defining the general state of the art which is not considered to be of particular relevance
- "E" earlier document but published on or after the international filing date
- "L" document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)
- "O" document referring to an oral disclosure, use, exhibition or other means
- "P" document published prior to the international filing date but later than the priority date claimed

T later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention

X document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone

Y document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art.

& document member of the same patent family
